

STA 291
Lecture 27

- **Final exam 6:00-8:00PM Thursday May 6**
- **Room: will be in the Classroom Building**

- Makeup final exam: Friday May 7
- 10:00am – 12:00 noon

Last online Homework

- **Last Online homework assignment will be posted this week**

STA 291 - Lecture 27

4

Example: two sample test

- **Comparing Two Populations**
 - *Two Independent Samples (not paired)*

STA 291 - Lecture 27

5

Chap.13 Comparison of Two population means with Independent Samples

- Two **Independent** Samples (**not paired**)
 - Different subjects in the different samples
 - Two subpopulations (e.g., male/female)
 - The two samples constitute independent samples from two subpopulations, sample size can be different and often are different

STA 291 - Lecture 27

6

Example

- Weight gain (grams) of female rats between 28 and 84 days after birth. 12 were fed with high protein diet, 7 were fed with low protein diet.
- High protein: 134, 146, 104, 119, 124, 161, 107, 83, 113, 129, 97, 123.
- Low protein: 70, 118, 101, 85, 107, 132, 94.

STA 291 - Lecture 27

7

- Two samples. un-equal sample size.
Parameters: 2 mu's (the population mean values)

$$H_0 : \mu_1 = \mu_2$$

(two sided) $H_A : \mu_1 \neq \mu_2$

- Compute $t_{\text{obs}} = 1.891436$
- P-value = 0.0757 (use two sided formula)

STA 291 - Lecture 27

8

- This calculation of t_{obs} can be done by calculator,
- But more often by a software.
- Besides, an extensive t-table is not always available on paper.

STA 291 - Lecture 27

9

- Sometime we just report a P-value.
- So, in this example if we decided to use $\alpha=0.05$ the conclusion would be “not reject H_0 ”, since 0.0757 is NOT less than α

STA 291 - Lecture 27 10

- Sample size is small. Here 12 and 7.
- Have to use t-table, (the substitute of Z-table would result in large errors)
- Usually done by software. We are not required to work with software in sta291 exam, but we should be able to work out everything else given the computer output, or P-value.

STA 291 - Lecture 27 11

Confidence Interval for the Difference of Two Means: Example

- In the 1982 General Social Survey, 350 subjects reported the time spent every day watching television. The sample mean was 2.7 hours, with standard deviation 2.1
- In the 1994 General Social Survey, 395 subjects reported a mean time spent watching television of 3.5 hours, with standard deviation 2.5
- *Is it plausible that the mean was the same in both years?*

STA 291 - Lecture 27 12

- both mu's unknown (for year 1982 and 1994) since we never was sure about the year 1982. (no census was done)
- Two sided alternative. We did not see something like "was average TV time *increased*". The default one is to use two-sided alternative

$$H_A : \mu_1 \neq \mu_2$$

- TV programs are getting better, but other competing form (internet, computers etc) getting the people away from TV

Significance Test for the Difference of Two Means

- Let μ_1 be the mean in 1982, and μ_2 be the mean in 1994

$H_0 : \mu_1 = \mu_2$ which is equivalent to $H_0 : \mu_2 - \mu_1 = 0$,

$$t_{obs} = \frac{\bar{X}_2 - \bar{X}_1}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}}$$

$$\frac{2.7 - 3.5}{\sqrt{\frac{2.1^2}{350} + \frac{2.5^2}{395}}} = -4.745$$

- P-value = $2P(Z > 4.745) = 0.000002085$

or less than $2 \times 0.000? = 0.000?$ by our Z table

- Highly significant!
- Strictly speaking I should look up the t-table.... P-value = 0.00000250
- Did not change our conclusion.

- In general when sample size(s) > 100, normal table and t-table are very similar

- Will have one (or two) long question that is not multiple choice.
- This is where you can earn partial credit even if the final answer is wrong

- Get prepared by reviewing
 - **Formula sheets**
 - **Lecture notes**
 - **The first two exams**
 - **Online homework questions**
 - **Material from lab sessions**
 - **Textbook**
 - **Old exams**

- Testing hypothesis (we covered 4 cases)

Null and alternative hypothesis

P-value, significance

Type I and type II errors

- Computation of the test statistic:

either z or t (follow formula sheet)

And table

Multiple choice Q

- If a test turns out to be significant at alpha-level 0.01. (what exactly this mean for the p-value?)
- Will the same test also be significant at 0.05 level?

- P-value is **NOT** the probability that the H_0 is true.

- A small p-value mean that we saw something happened that is **hard to explain** by H_0 (a small probability event)

- A large p-value do not automatically means H_0 is true. (2 possibilities: either H_0 is true or there is too few data/info)

Correspondence Between Confidence Intervals and Tests

Only apply to 2-sided alternative hypothesis setup.

But works for either proportion "p" or mean "mu". In fact this correspondence is valid in much wider context.

STA 291 - Lecture 27

25

- Confidence intervals:

Interpretation, coverage probability, confidence level

Student t-confidence interval

STA 291 - Lecture 27

26

Attendance Survey Question

- Please write down your name and section number
- Today's Questions

- DO you like to use software in sta291?

STA 291 - Lecture 27

27

Exam II curve: conversion formula

- If your original score is 83 or above, then converted score is $= 90 + (x - 83)10/17$
- If your original score is 71 \rightarrow 82, then converted score is $= 80 + (x - 71)9/11$
- If your original score is 59 \rightarrow 70, then converted score is $= 70 + (x - 59)9/11$
- If your original score is 48 \rightarrow 58, then converted score is $= 60 + (x - 48)9/10$
- If your original score is 1 \rightarrow 47, then converted score is $x \cdot 59/47$
